Run wheel file in SONiC	8

Introduction

This guide will serve as an example of how you can test and validate your changes to sonic-utilities package – in particular the changes related to the CLI. Command-line utilities code is packaged inside a python wheel file that we can deploy in SONiC. The first step is to build the wheel package containing source code changes that you might want to test in SONiC.

Building a wheel package containing your source code, and running it into SONiC is trivial, but this guide will show how to run unit tests related to CLI to validate your changes. Running unit tests require a lot of dependencies to be met, those that are tedious to keep track of manually. A convenient alternative is to let the build process of sonic-buildimage repo take care of that for you. During the build process, the SONiC build process will take care of all the necessary dependencies and install them inside of a container (known as sonic-slave container). The idea is to stay inside the container once the build process starts to make the utilities wheel file and run unit tests inside this environment.

Environment

OS: Ubuntu 20.04

Dependencies

1. Install git, pip3 and jinja in host build machine
sudo apt install git
sudo apt install -y python3-pip
sudo pip3 install j2cli
2. Install [Docker](#) and follow [post-installation steps](#) to allow running the 'docker' command without root privileges.
Validate that docker can run without 'sudo' through the command line
sudo gpasswd -a \${USER} docker
docker run hello-world

Build sonic-utilities wheel package

Build locally

1. Clone the sonic-buildimage repository and navigate to the local repo through the command line

git clone <https://github.com/sonic-net/sonic-buildimage>

cd sonic-buildimage

2. To clone your own fork of sonic-net repository, you can edit the .gitmodules file inside the root directory

vi .gitmodules

Edit the “Url” field of the submodule for which you wish to clone your own fork of the repository. Here you will want to change the Url field of the sonic-utilities submodule.

3. Initialize the repository through the command

make init

Note that this step may take hours depending on your internet connection, so please be patient.

This step will clone all of the submodules listed in the .gitmodules file inside the src/ directory. After the command completes, head into src/sonic-utilities directory and inspect that you got your own fork of the repository. If the code you wish to build is in another branch, change the branch using

git checkout <branch_name>

4. Configure the build environment for an ASIC type (any platform will do here for sonic-utilities)

make configure PLATFORM=generic

5. Make the sonic-utilities wheel file while keeping the Bullseye slave container alive to run unit tests in it.

make NOSTRETCH=1 NOBUSTER=1 KEEP_SLAVE_ON=yes target/python-wheels/bullseye/sonic_utilities-1.2-py3-none-any.whl

6. When the build finishes, your prompt will change indicating you are inside the sonic-slave container. Navigate to sonic-utilities directory inside the src folder.

cd src/sonic-utilities

7. Now you can make changes inside VS Code or your preferred code editor inside the sonic-buildimage/src/sonic-utilities directory.

8. To test your changes, run the command inside the sonic-slave container

python3 setup.py test

The above command will run all the unit tests associated with SONiC CLI. To run an **individual test** you can use the command

pytest-3 tests/<name_of_test_file>

Useful options to above command

-vv: Verbose output. Shows all of the individual functions run within the file.

-rP: Show standard output while running the test.

e.g. **pytest-3 -rP -vv tests/vlan_test.py**

9. Some tests may fail while running tests/building sonic-utilities in a local environment, they are:

- FAILED tests/disk_check_test.py::TestDiskCheck::test_readonly
- FAILED tests/drops_group_test.py::TestDropCounters::test_show_counts
- FAILED tests/drops_group_test.py::TestDropCounters::test_show_counts_with_group
- FAILED tests/drops_group_test.py::TestDropCounters::test_show_counts_with_type

These tests pass in Azure pipelines under the same piece of code, so you can safely ignore them in a local build if they appear as FAILED.

10. If the rest of the tests pass, you can be sure that the changes are valid and will not cause the SONiC CLI to break. After validating the changes, you can run build the utilities wheel file through the command

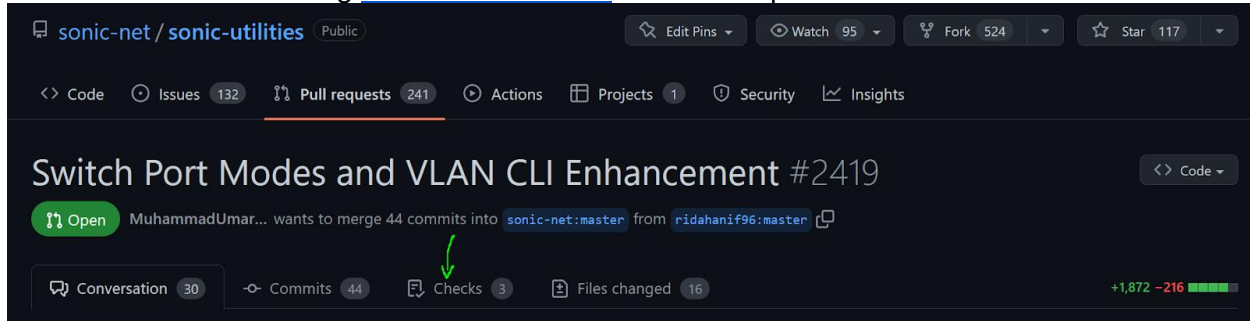

python3 setup.py bdist_wheel

The wheel file will be created under sonic-utilities/dist directory.

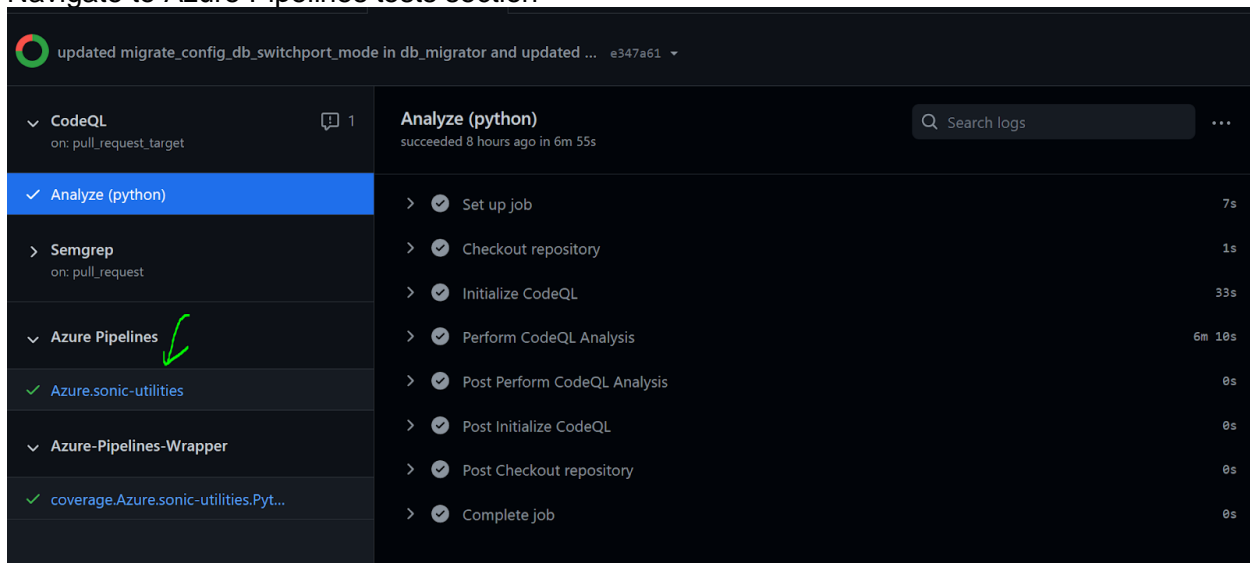

Build through CI/CD Pipelines

You can also create a draft PR on the actual [sonic-utilities](#) repository on GitHub. The changes will automatically pass through the Azure CI Pipelines upon pushing a commit.

To see the output of the tests or to monitor the tests as they are running, you can navigate to 'Checks' section. I'm using [sonic-utilities#2419](#) as an example PR.

Navigate to Azure Pipelines tests section

You may scroll down now to find the link to the Azure Pipelines

Switch Port Modes and VLAN CLI Enhancement #2419
 updated migrate_config_db_switchport_mode in db_migrator and updated ... e347a61

on: pull_request

Azure Pipelines

Azure.sonic-utilities

Azure-Pipelines-Wrapper

0 errors / 1 warnings

DETAILS

Tests

- Failed: 0 (0.00%)
- Passed: 2,200 (99.86%)
- Other: 3 (0.14%)
- Total: 2,203

Code coverage

- 8630 of 14324 branches covered (60.25%)
- 28642 of 40115 lines covered (71.40%)

 3 Duration: 15m 44s
 4
 5 Job preparation parameters
 6 8 queue time variables used
 7 2 artifacts produced
 8 99.8% tests passed

If all the tests pass, you will have a downloadable artifact containing the wheel file to run on SONiC

Download the artifact

Under the summary section, you can find the list of produced artifacts and download them on your local machine.

The screenshot shows the Azure DevOps interface for a build. The left sidebar contains navigation links: build, Overview, Boards, Repos, Pipelines, Pipelines (selected), Releases, and Artifacts. The main content area shows the build summary for a pipeline named "#20230225.4 • Switch Port Modes and VLAN CLI Enhancement" by Azure.sonic-utilities. A message states: "This run is being retained as one of recent runs by pipeline." with a "View retention leases" link. Below this, the "Summary" tab is active, showing a pull request by MuhammadUmarAsad. It includes details about repositories (sonic-net/sonic-utilities, +1), time started and elapsed (Yesterday at 3:41 PM, 15m 55s), related work items (0 published, 1 consumed), and test coverage (99.8% passed, 71.40% covered). A "Warnings" section shows a warning about ignoring coverage report directory with HTML content. At the bottom, a "Jobs" table is partially visible with columns for Name, Status, and Duration.

You can download the “**wheels**” artifacts that would be a zip file containing the sonic-utilities wheel file produced as a result of the build run.

The screenshot shows the Azure DevOps Artifacts page. The left sidebar has a back arrow and the word "Artifacts". Below it, there are tabs for "Published" (selected) and "Consumed". A table lists artifacts with columns for Name, Status, and Duration. The table contains two rows: "Code Coverage Report_224449" and "wheels". A dropdown menu is open next to the "wheels" artifact, showing options: "Download artifacts" and "Copy download URL".

Extract the wheel file into a file into a folder and follow the next instructions to run it on SONiC.

Note: The build run is cleaned after a few days, so the artifacts generated through this method are available for a limited time. They would be re-run if a new commit is pushed thereby generating a fresh artifact.

Run wheel file in SONiC

To incorporate the changes into SONiC, you need to replace the existing sonic-utilities package inside the OS with your newly created package.

1. Start a SONiC instance and log in with your credentials.

2. Delete the current CLI package through pip

sudo pip uninstall sonic_utilities

3. Navigate to the directory where the newly created wheel file is located. Run a python web server inside the directory to install it into SONiC through the web.

python3 -m http.server <port> --bind <ip_address>

Example:

.168.1.64

4. Install the wheel file inside SONiC through the command

sudo pip install http://<ip_addr>:<port>/sonic_utilities-1.2-py3-none-any.whl
sudo pip install http://192.168.0.197:8000/sonic_utilities-1.2-py3-none-any.whl

sudo pip3 install --force-reinstall --no-deps http://172.16.7.13:8000/sonic_utilities-1.2-py3-none-any.whl

5. Voila! Your changes are now present inside SONiC.
